

PROGRAMMABLE SERIAL INTERFACE

Field of the Invention

The present invention relates to a method and/or  
5 architecture for point-to-point communication devices generally  
and, more particularly, to a programmable serial interface.

Background of the Invention

Point-to-point and point-to-multipoint communication  
10 devices allow for a transfer of data signals over high-speed serial  
links. Each transmit channel of the communication devices receives  
parallel data signals at an input, converts the parallel data  
signal to a serial data signal and transmits the serial data signal  
to a receiving channel. Each receiving channel of the  
15 communication devices receives the serial data signal from a  
transmit channel, converts the serial data signal back into the  
parallel data signal and presents the parallel data signal.

Pre-transmission processing and post-reception processing  
of the parallel data signals are conventionally performed outside  
20 the communication device in additional circuitry. Examples of  
processing performed by the additional circuitry include

0325.00485

CD01026

framing/de-framing, header insertion/removal, error encoding/detection and byte stuffing/de-stuffing. The presence of the additional circuitry consumes space, power and cost while decreasing reliability.

5           One approach to improve the space, power and reliability factors is designing an application specific communication device with built-in pre-transmission processing and the post-reception signal processing. Disadvantages of the application specific approaches include increased design costs and fixed signal processing functionality. What is desired is a low-cost communication device where the signal processing is programmable to adapt to a wide variety of applications.

#### Summary of the Invention

15           The present invention concerns a programmable serial interface device. The device generally comprises a programmable logic device and another die mounted to an assembly apparatus. The programmable logic device may comprise (i) a plurality of logic block clusters and (ii) a plurality of routing channels configured  
20           to interconnect said logic block clusters. The die may comprise a first communication channel (i) configured to convert between a

0325.00485

CD01026

first serial data signal and a first parallel data signal and (ii) coupled to a first of the routing channels to exchange the first parallel data signal with at least one of the logic block clusters.

The objects, features and advantages of the present invention include providing a method and architecture for a communication device that may be (i) low cost, (ii) programmable, (iii) high speed and/or (iv) a single package device.

#### Brief Description of the Drawings

These and other objects, features and advantages of the present invention will be apparent from the following detailed description and the appended claims and drawings in which:

FIG. 1 is a block diagram of a device implementing the present invention;

FIG. 2 is a detailed block diagram of a complex programmable logic device;

FIG. 3 is a detailed block diagram of a communication die; and

FIG. 4 is a flow diagram of a method of fabricating the device.

**Detailed Description of the Preferred Embodiments**

Referring to FIG. 1, a block diagram of a device 100 is shown in accordance with a preferred embodiment of the present invention. The device 100 generally comprises a circuit (or die) 102 and a circuit (or die) 104 mounted on an assembly apparatus 105. The circuit 102 may be implemented as a programmable die and the circuit 104 may be implemented as a serial communication die. For example, the circuit 102 may be implemented as a logic device, a complex programmable logic device (CPLD), a field programmable gate array, or the like. The circuit 104 may be implemented as a point-to-point communication device, a point-to-multipoint communication device, a serial transceiver, or the like. For the purposes of illustrating the present invention, the circuit 102 may hereinafter be referred to as a CPLD 102. The circuit 104 may hereinafter be referred to as a serialization/deserialization circuit or SERDES 104 for short. The assembly apparatus 105 may be implemented as a ceramic substrate, a metal or plastic housing, or the like.

The CPLD 102 may have an interface 106 to exchange one or more signals (e.g., IN and OUT) with an interface 108 of the SERDES 104. The CPLD 102 may have an additional interface 110 to exchange

0325.00485  
CD01026

signals (e.g., CNTR, RESP and DATA) externally to the device 100.  
The SERDES 104 may have an interface 112 to exchange one or more  
signals (e.g., TX and RX) externally to the device 100.

The signal IN may comprise multiple signals (e.g., AIN,  
BIN, CIN and DIN), one for each communication channel of the SERDES  
104. The signal OUT may comprise multiple signals (e.g., AOUT,  
BOUT, COUT and DOUT), one for each communication channel of the  
SERDES 104. The signal TX may comprise multiple signals (e.g.,  
TXA, TXB, TXC and TXD), one for each communication channel of the  
SERDES 104. The signal RX may comprise multiple signals (e.g.,  
RXA, RXB, RXC and RXD), one for each communication channel of the  
SERDES 104. The signal DATA may comprise one or more individual  
data signals flowing into and from the CPLD 102. The signal CNTR  
may comprise one or more individual control signals received by the  
CPLD 102. The signal RESP may comprise one or more response  
signals presented by the CPLD 102.

The CPLD 102 may receive the signal DATA and signal CNTR  
prior to transmission. The CPLD 102 may perform pre-transmission  
processing of the signal DATA in accordance with the signal CNTR to  
produce the signal OUT. The CPLD 102 may present the signal OUT to  
the SERDES 104. The SERDES 104 may convert the signal OUT from a

0325.00485  
CD01026

parallel format into the signal TX having a serial format. The SERDES 104 may then transmit the signal TX.

The SERDES 104 may receive the signal RX at the start of reception. The SERDES 104 may convert the signal RX from the serial format into the signal IN having the parallel format. The SERDES 104 may then present the signal IN to the CPLD 102. The CPLD 102 may perform post-reception processing on the signals IN to produce at least one of the signal DATA and the signal RESP. The CPLD 102 may then present the signal DATA and/or the signal RESP externally to the device 100.

Programming of the device 100 may be performed by any conventional method suitable for the particular implementation of the CPLD 102 and the SERDES 104, if programmable. The programming may be performed during a one-time download process or repeatedly during each power-up, depending upon the capabilities of the CPLD 102 and the SERDES 104. Programming of the CPLD 102 may define the pre-transmission processing and/or the post-reception processing. Programming examples for the SERDES 104 may include, but are not limited to, set-up parameter initialization, encoding/decoding selection, baud rate, parity generate/check, input clocking

0325.00485  
CD01026

options, output clocking options, skew alignment, serial signaling rate and multi-communication channel bonding options.

The CPLD 102 may comprise multiple logic block clusters 114 (designated as "CL"), multiple routing channels 116 and multiple I/O banks 118. The logic block clusters 114 may be arranged in a one or two dimensional array. The routing channels 116 may be disposed between horizontally and/or vertically adjacent logic block clusters 114. The I/O banks 118 may be disposed around the outer edge of the CPLD 102. Each of the I/O banks 118 may be coupled to one or more of the routing channels 116.

The routing channels 116 may be dynamically configured to transfer signals among the logic block clusters 114 and the I/O banks 118. For example, the routing channels 116 may convey signals between a particular I/O bank 118 and one or more of the logic block clusters 114. In another example, the routing channels 116 may convey signals among individual logic block clusters 114. The signals may be carried from a source to a destination or multiple destinations by a single routing channel 116 or multiple routing channels 116. The routing channels 116 generally move the signals in the parallel format, although the signals may be moved

0325.00485  
CD01026

in the serial format to meet the design criteria of a particular application.

5 The signal processing may be performed by the logic block clusters 114. One or more logic block clusters 114 may be programmed to operate on one or more signals IN, OUT, DATA, CNTR and/or RESP. The individual logic block clusters 114 may operate independently from each other and/or in cooperation with each other depending upon the programming. Examples of pre-transmission processing may include, but are not limited to, header insertion, byte stuffing, forward error code generation, framing, code piercing, convolution encoding, encryption, data to symbol conversion and block staggering. Examples of post-reception processing may include, but are not limited to, header removal, byte de-stuffing, error detection, error correction, de-framing, pierced code insertion, convolution decoding, decryption, symbol to data conversion and block reorganizing.

Each of the logic block clusters 114 may comprise multiple logic blocks, a programmable interconnect matrix, a channel memory block and multiple cluster memory blocks (not shown). Each of the logic blocks may comprise basic programmable logic functions such as product term arrays, product term

0325.00485  
CD01026

allocators and macrocells (not shown). The cluster memory blocks and the channel memory blocks may each comprise any mixture of volatile and non-volatile memory. Other configurations within the CPLD 102 may be implemented to meet the design criteria of a particular application.

Referring to FIG. 2, a detailed block diagram of an example circuit implementing the CPLD 102 is shown. Each of the I/O banks 118 generally comprises two or one and a half I/O blocks 120. The FIG. 2 shows an example having fourteen I/O blocks 120 within eight I/O banks 118. Each of the I/O blocks 120 may be associated with one of the routing channels 116. A combination of two half I/O blocks (e.g., 120A and 120B) may also be associated with one of the routing channels 116. Other configurations of I/O blocks 120 within the I/O banks 118 may be implemented to meet the design criteria of a particular application.

Each of the I/O blocks 120, including the half I/O blocks 120, may comprise multiple I/O cells (not shown). Generally, there may be one I/O cell for each bit transferred by the associated routing channel 116. Each of the I/O cells may be programmable to receive or present the bit synchronously or asynchronously. Multiple I/O cells may be operated together to exchange the signals

0325.00485  
CD01026

CNTR, RESP, DATA, IN and OUT with the parallel format. Individual I/O cells may be programmed to exchange other signals having a one bit width.

Referring to FIG. 3, a detailed block diagram of an example circuit implementing the SERDES 104 is shown. The SERDES 104 generally comprises one or more channels 122. In one example, the SERDES 104 may have four channels 122A-D. Each channel 122 may comprise a transmit communication channel 124 and/or a receive communication channel 126.

The transmit communication channel 124 may receive a signal (e.g., TXDn[7:0], where n identifies the channel A-D). The transmit communication channel 124 may receive another signal (e.g., TXCTn[1:0], where n identifies the channel A-D). The combination of the signal TXDn[7:0] and the signal TXCTn[1:0] may form the signal nOUT, where n identifies the channel A-D.

The signal TXDn[7:0] may be implemented as a data signal having a parallel format and conveying information to be transmitted. The signal TXCTn[1:0] may be implemented as a control signal. The signal TXCTn[1:0] may identify how the signal TXDn[7:0] characters are to be interpreted. In one example, the signal TXCTn[1:0] may be an encoding selection signal that may

0325.00485  
CD01026

indicate that the signal TXDn[7:0] is to be encoded as data or a special character code. In another example, the signal TXCTn[1:0] may disable data encoding and in turn may contain two additional bits of the data signal to be transmitted.

5           The transmit communication channel 124 may present a signal (e.g., OUTn1, where n identifies the channel A-D). The transmit communication channel 124 may present another signal (e.g., OUTn2, where n identifies the channel A-D). One or both of the signals OUTn1 or OUTn2 may be presented as the signal TXn, where n identifies the channel A-D. The signal TXn may have a serial format.

10           The transmit communication channel 124 may comprise a circuit 128, a circuit 130, a circuit 132 and a circuit 134. The circuit 128 may be implemented as a phase align buffer. The circuit 130 may be implemented as an encoder. The circuit 132 may be implemented as a serializer. The circuit 134 may be implemented as a dual differential line driver.

15           The phase align buffer 128 may provide synchronization between the signals TXDn[7:0] and TXCTn[1:0] and a clock signal (e.g., REFCLK). The encoder 130 may provide for 8B/10B encoding of the signal TXDn[7:0]. The serializer 132 may convert the encoded

0325.00485  
CD01026

data signal from the parallel format to the serial format. The line driver 134 may present the serial data signal as the signals OUTn1 and OUTn2.

The receive communication channel 126 may receive a signal (e.g., INn1, where n identifies the channel A-D). The receive communication channel 126 may receive another signal (e.g., INn2, where n identifies the channel A-D). One or both of the signals INn1 or INn2 may form the signal RX. The signal RX may have a serial format.

The receive communication channel 126 may present a signal (e.g., RXDn[7:0], where n identifies the channel A-D). The receive communication channel 126 may present another signal (e.g., RXSTn[2:0], where n identifies the channel A-D). The combination of the signals RXDn[7:0] and RXSTn[2:0] may form the signal nIN, where n identifies the channel A-D. The signal RXDn[7:0] may be implemented as a data signal having the parallel format and conveying the information received. The signal RXSTn[2:0] may be implemented as a status signal. In one example, the signal RXSTn[2:0] may indicate decoding of the signal RXDn[7:0] as the data signal or the special character code. In another example, the

0325.00485

CD01026

signal RXSTn[2:0] may transfer two bits of the data signal when the decoding is disabled.

The receive communication channel 126 may comprise a circuit 136, a circuit 138, a circuit 140, a circuit 142 and a circuit 144. The circuit 136 may be implemented as a dual differential line receiver. The circuit 138 may be implemented as a deserializer. The circuit 140 may be implemented as a framer. The circuit 142 may be implemented as a decoder. The circuit 144 may be implemented as an elasticity buffer.

The line receiver 136 may receive the signals INn1 and INn2. The deserializer 138 may convert the received signals from the serial format to the parallel format. The framer 140 may detect boundaries of a frame of data and extract the data signal. The decoder 142 may perform 8B/10B decoding of the extracted data signal. The elasticity buffer 144 may provide for buffering of the data signal, status signal and any error detection bits between an output of the decoder 142 and the presentation of the signals RXDn[7:0] and RXSTn[2:0], where n identifies the channel A-D.

Referring to FIG. 4, a flow diagram of a method of fabricating the device 100 is shown. The process may begin by providing the CPLD 102, the SERDES 104, the assembly apparatus 105

0325.00485  
CD01026

and any other die and/or components (e.g., a lid, bonding wire, capacitors, resistors and such) to be used during the assembly (e.g., block 146). The CPLD 102, SERDES 104 and the other components may then be mounted on the assembly apparatus 105 (e.g., block 148). Connections may be created between the CPLD 102, SERDES 104, assembly apparatus 105 and the other components (e.g., block 150). The connections may include coupling the communications channels 124 and 126 of the SERDES 104 with the routing channels 116 of the CPLD 102. The coupling between communication channels 124 and 126 and routing channels 116 may have a one-to-one relationship. Each communication channel 124 and 126 may be coupled through an I/O block 120 to one routing channel 116.

After the connections have been made, the device 100 may be tested (e.g., block 152). If the device 100 passes the testing step, then a cover may be attached to seal the device thus forming a completed package (e.g., block 154). In an alternative process, the cover may be attached prior to testing. Additional steps may be performed on the device 100 after attaching the cover to meet the criteria of a particular fabrication and test process. Optionally, the device 100 may then be programmed to meet the

0325.00485  
CD01026

requirements of a particular application specified by a customer.  
Alternatively, the device 100 may be supplied to the customer  
unprogrammed.

5 The various signals of the present invention may be  
implemented as single-bit or multi-bit signals in a serial and/or  
parallel configuration.

While the invention has been particularly shown and  
described with reference to the preferred embodiments thereof, it  
will be understood by those skilled in the art that various changes  
in form and details may be made without departing from the spirit  
and scope of the invention.
